## ABSTRACT

The White Devil gold mine located about 40km northwest of Tennant Creek, Northern Territory, is currently being developed by Australian Development Limited following a successful exploration program in an area of former mining.

The well-bedded siliciclastic sedimentary rocks of the Lower Proterozoic Warramunga Group, which host the White Devil mineralization, have undergone two main deformations. The early ductile deformation ( $D_1$ ) was a moderate deformation, which produced upright east-west trending open-close folds, with a regular plunge 40-50° toward 245°. The late semi-ductile to brittle deformation ( $D_2$ ) was a continuous deformation, which was associated with at least three closely spaced events. These were the intrusion of a set of semi-concordant porphyries, an early east-west upright shearing associated with the emplacement of hydrothermal quartz-magnetite bodies (ironstone) and a progressive shearing associated with the mineralization. The shearing produced a slickenside/fibre lineation, that suggests a vertical-oblique displacement with the south block eastwardly uplifted and the north block westwardly downthrown.

The gold-bismuth-copper mineralization in the White Devil deposit was formed during the progressive deformation ( $D_2$ ) and was mainly associated with the long thin magnetite-rich bodies and extended in varying degrees into the associated chloritized sediments, especially within the shear zone.

Studies of mineral textures, fluid inclusions, chlorite compositions and sulphur isotopes have provided information for a preliminary interpretation of ore-forming conditions and some indications of evolution of the hydrothermal fluid. Textural relationships and fluid inclusion data demonstrate that there were two distinct phases of the hydrothermal fluid. The magnetite was formed from a fluid of relatively high temperature (~400°C) and high salinity (probably  $\text{CaCl}_2\text{-NaCl}$ ). The gold-bismuth-copper mineralization was formed from a fluid of lower temperature (~300°C) and moderate salinity (probably NaCl-rich). Analyses of chlorite associated with the ore confirm the fluid inclusion temperatures and indicate  $\log f\text{O}_2$  and  $\log f\text{S}_2$  conditions of approximately -31.6 to -35.0 and -9.8 to -11.6, respectively. A magmatic component to the fluid is suggested from preliminary sulphur isotope data.

Under the proposed T- $f\text{O}_2$ -pH conditions of the fluid, gold transport would be predominantly by means of the  $\text{AuCl}_2^-$  complex. Deposition of gold was probably controlled by decrease of fluid temperature and/or increase in pH. The close association of the orebody and the magnetite suggests that the magnetite may also be an important factor, in that in some way, it could have acted as a chemical trap for the ore deposition.

# CONTENTS

	PAGE
CHAPTER 1: INTRODUCTION	
1.1.Location of the study area .....	1
1.2.History and previous investigation.....	1
1.3.Aims of study.....	2
1.4.Methods.....	3
CHAPTER 2: GEOLOGY OF THE BLACK ANGEL AND WHITE DEVIL AREAS	
2.1.Introduction.....	4
2.2.Lithological descriptions.....	4
2.2.1.The Warramunga Group sediment.....	4
2.2.2.Quartz-feldspar-porphyry.....	6
2.2.3.Ironstone and the associated chloritized sediment .....	8
a.Ironstone.....	8
b.Chloritized sediment .....	9
CHAPTER 3: STRUCTURAL GEOLOGY	
3.1.Introduction.....	10
3.2.The first deformation $D_1$ .....	10
3.3.The second deformation $D_2$ .....	12
3.3.1.Intrusion of porphyries.....	13
3.3.2.Early shearing associated with the emplacement of magnetite .....	13
3.3.3.Progressive shearing associated with Au-Bi-Cu mineralization.....	14
3.3.4.Structural relationship in second deformation .....	16
CHAPTER 4: FRACTURE ANALYSIS	
4.1.Introduction .....	19
4.2.Fracture analysis .....	19
4.2.1.Fractures with slickensides .....	19
4.2.2.Planar fractures.....	20
4.2.3.Curvated fractures.....	21

## CHAPTER 5: MINERALIZATION OF THE WHITE DEVIL MINE

5.1.Setting of the ore body .....	22
5.2.Mineral zonation .....	23
5.2.1.Massive magnetite-chlorite .....	23
5.2.2.Chloritized sediment .....	23
5.2.3.Ore mineral zonation .....	24
5.3.Ore textures.....	24

## CHAPTER 6: GEOCHEMISTRY OF THE WHITE DEVIL MINE

6.1.Fluid inclusion study .....	26
6.2.Sulphur isotope study .....	28
6.3.Chlorite analysis .....	29
6.4.Geochemistry of the hydrothermal fluid.....	30
6.5.Summary of ore forming conditions .....	31

## CHAPTER 6:DISCUSSION AND PROPOSED GENETIC MODEL 32

## ACKNOWLEDGEMENT ..... 36

## REFERENCES ..... 37

## APPENDIX 1: THIN SECTION DESCRIPTIONS ..... 42

## APPENDIX 2: STRAIN ANALYSIS, FRY METHOD ..... 53

## APPENDIX 3: FLUID INCLUSION DATA..... 54

## APPENDIX 4: CHLORITE AND TALC ANALYSES ..... 56

## LIST OF PLATES

- PLATE 1: Coarse-grained greywacke with "rough" cleavage.
- PLATE 2: Siltstone with slaty cleavage.
- PLATE 3: Pencil cleavage in siltstone.
- PLATE 4: Shear zone with vertical schistosity  $S_2$ .
- PLATE 5: Fibrous quartz in a net-vein stockwork.
- PLATE 6: Massive graded bedding in sandstone.
- PLATE 7: Vertical discrete schistosity  $S_2$  and vertical polished-slickenside shear surface.
- PLATE 8: Slumping and sliding due to soft sediment deformation.
- PLATE 9: Fractures on a horizontal surface.
- PLATE 10: Fractures on a vertical surface.
- PLATE 11: A magnetite vein in the western porphyry.
- PLATE 12: Orthogonal fractures in ironstone.
- PLATE 13: Massive porphyry.
- PLATE 14: Foliated porphyry.
- PLATE 15: Green chloritic shear zone.
- PLATE 16: Underground photo of foliated porphyry.
- PLATE 17: Microphoto of rough cleavage in sandstone.
- PLATE 18: Quartz grain with mica beards and pressure solution.
- PLATE 19: Sharp boundary between sandstone and siltstone.
- PLATE 20: Silicified siltstone with heavy minerals in layer laminae.
- PLATE 21: Magnetite vein in chloritic shear zone.
- PLATE 22: Microcrack-seal vein in magnetite.
- PLATE 23: Microphoto of massive porphyry.
- PLATE 24: Microphoto of sheared porphyry.
- PLATE 25: Silicified rock from the surface (SEM photo).
- PLATE 26: Slaty cleavage developed in shale (SEM photo).
- PLATE 27: Magnetite developed in chloritic shear zone (SEM photo).
- PLATE 28: Slickenside surface (SEM photo).
- PLATE 29: Early coarse-grained and later fine-grained chlorite in the shear zone (SEM).
- PLATE 30: Relationship of magnetite and chlorite in the shear zone (SEM photo).
- PLATE 31: Sigmoidal tension cracks developed in magnetite (SEM photo).
- PLATE 32: Chlorite intergrowth with bismuthinite (SEM photo).
- PLATE 33: Pseudo-slumped structure in magnetite.
- PLATE 34: Bi-Cu mineralization with chalcopyrite and bismuthinite occupying fractures.

- PLATE 35: Granular aggregated magnetite and euhedral pyrite.
- PLATE 36: Co-precipitated gold, chalcopyrite and bismuthinite .
- PLATE 37: Visible gold, chalcopyrite and bismuthinite developed in fracture.
- PLATE 38: A large tension crack filled by chlorite, pyrite and chalcopyrite.
- PLATE 39: Section of copper rich mineralization.
- PLATE 40: Section of talc-dolomite zone.
