Abstract

The skin extracts from amphibians have been investigated for over fifty years and have been found to contain numerous components with therapeutic and medicinal uses. Host-defence compounds are secreted onto the dorsal surface of the animal from specialised granular glands in response to a variety of stimuli, such as stress induced by a predator. Isolated peptides can exhibit either pharmacological properties or antibiotic activity.

Previous studies isolated a potent hypotensive neuropeptide, crinia angiotensin II, within skin secretions of the Australian frog *Crinia georgiana*. This prompted further investigations into the isolation and sequence determination of host-defence compounds from other species in this genus- *C. signifera*, *C. riparia* and *C. deserticola*. Fifteen novel peptides were identified. The major peptide components were potent disulfide containing neuropeptides of a type not observed in other Australian anurans that have been previously investigated. The remaining peptides demonstrate either antibiotic activity or inhibit the enzyme neuronal nitric oxide synthase.

The skin components from anurans of the *Litoria* genus have been extensively studied, with a number of peptides exhibiting both antibacterial and pharmacological activity. The skin secretion of *Litoria dentata* has been investigated, with five novel peptides identified. The neuropeptide tryptophyllin L 1.3 was previously isolated from the related frog *L. rubella*. Other components that are unique in structure have not yet been tested for biological activity.

The parasitic disease malaria is responsible for over one million deaths per year. The increase in resistance of current antimalarial compounds has led to the development of new treatments from various animal-derived peptide antimicrobials. A number of amphibian peptides and their derivatives were investigated as potential antiplasmodial agents against the malaria parasite *Plasmodium falciparum*. Results indicate that these compounds inhibit parasite growth with minimal haemolytic activity, making them promising tools for malaria research.

The defence chemistry of amphibian neuropeptides has been extensively studied and is important in understanding both the ecology and physiology of the vertebrate. Neuropeptides are classified into groups with similar structural characteristics. Biological activity occurs via interaction with a G protein-coupled receptor. The most studied of all amphibian neuropeptides is caerulein, which has a similar spectrum of activity to the mammalian peptide cholecystokinin. This includes smooth muscle contraction that occurs via interaction with cholecystokinin receptors.

The pharmacological activity of Australian anuran neuropeptides from various genera was investigated. Two biological assays were conducted- a smooth muscle contraction test and a lymphocyte proliferation assay. A range of neuropeptides contracted smooth muscle at nanomolar concentrations, while others only proliferated lymphocytes. Some peptides were inactive in both assays.

Young marsupials are born at an immature stage of development and rely on immune protection provided by the mother. Eugenin is a host-defence compound isolated from pouch secretions of the Tammar wallaby. The immunomodulator activates CCK₂ receptors, resulting in lymphocyte proliferation. Therefore, eugenin stimulates immune cells in the pouch providing vital immune protection for pouch young.

Statement of Originality

This thesis contains no material that has been accepted for the award of any other degree or diploma in any university or other tertiary institution and, to the best of my knowledge and belief, contains no material previously published or written by another person, except where due reference has been made in the text.

I give consent for this copy of my thesis, when deposited in the University Library, to be available for loan and photocopying.

Acknowledgements

I would like to thank my supervisor, Professor John H. Bowie, for allowing me the opportunity to undertake a Ph.D. and conduct research in such an interesting and diverse field. I have enjoyed the experience and gained immensely from it.

Special thanks to Dr. Ian F. Musgrave, from the Department of Experimental and Clinical Pharmacology, University of Adelaide, for his assistance with the pharmacological aspects of this work. Thank you for donating your time.

In addition, I would like to thank Associate Professor Michael J. Tyler, from the Department of Environmental Biology, University of Adelaide, for providing frog specimens and skin secretions, and Dr. Leanne Tilley (Department of Biochemistry, La Trobe University) for her assistance with antimalarial tests.

Many thanks to both past and present members of the Bowie research group, especially those who assisted in the preliminary stages of my research in teaching me the required technical skills.

Special thanks to my family and friends for all the support and encouragement they have given me over this time. It has been greatly appreciated. Finally, I would like to thank my partner Chris. First, a big thanks for joining me on my frog hunt expeditions and collecting a record number of frogs. Thank you for your continual interest in my research, and for providing the much needed laughs and positive outlook when I lost focus. But most importantly, thank you for your love and belief in me.
