## Declaration

This work contains no material which has been accepted for the award of any other degree or diploma in any university or other tertiary institution to Manisha Dayal and, to the best of my knowledge and belief, contains no material previously published or written by another person, except where due reference has been made in the text.

I give consent to this copy of my thesis, when deposited in the University Library, being made available for loan and photocopying, subject to the provisions of the Copyright Act 1968. I also give permission for the digital version of my thesis to be made available on the web, via the University's digital research repository, the Library catalogue, the Australasian Digital Theses Program (ADTP) and also through web search engines, unless permission has been granted by the University to restrict access for a period of time.

## Abstract

Cranial sutures are fibrous joints of the skull which allow for growth in young individuals. The sutural ligament is the fibrous connective material found between the two joint surfaces which can be divided into a number of different layers. During embryonic development and growth, ossification centres in the skull allow for the growth and development of the flat bones in the skull. Sutures are the areas where these ossification centres eventually meet. Some sutures like the frontal suture normally disappear at the age of two years, but it has been shown that this suture can persist in adulthood and is then called the metopic suture. Torgersen (1950) has shown that the obliteration pattern of the metopic suture is the same for skulls belonging to common inheritance trajectories. Cranial suture closure has thus been shown to be controlled by genes. In physical anthropology, obliteration of cranial sutures has been used as an age-at-death indicator since 1542. However, in 1890, Dwight rejected the notion that there was any relationship between age and obliteration patterns. Despite this, there have been a number of studies that have continued to use this method to estimate age-at-death from skeletal remains. These methods are currently still being used. The aim of this study was to investigate cranial suture obliteration patterns in adult crania. A total of 490 randomly selected modern black and white South African skulls from the Dart Collection were used to collect data. The ages of the individuals ranged from 19 to 98 years. Two methods previously used to estimate age from skeletal remains were used to assess the final obliteration status of the sutures. The scores assigned to these sutures were then subjected to statistical analyses to explore any relationship between age, sex and population affinity. The results show that considerable polymorphism in the obliteration pattern

of the cranial vault sutures exist. The endocranial scores are bimodal while the ectocranial aspects using both the Acsádi & Nemeskéri (1970) and Meindl & Lovejoy (1985) method are multimodal. Bimodality and multimodality are direct indications of polymorphism. No significant relationship was found between obliteration and age. Thereafter the two methods initially used to assess the sutures were used to estimate the age of the skulls to test these methods. The results show that both these methods are not useful as age estimators when used on individuals drawn from the South African black and white populations. Since the large majority of variation in cranial suture obliteration is not explainable by age, it is hypothesized that patterns of the cranial vault suture obliteration are the result of epigenetic variation similar to that occurring elsewhere on the skeleton, and not a regular result of aging.

## **Acknowledgements**

### **Thank you**

This project would not have been possible without the generous donations of the many people that have donated their bodies to science and those who unknowingly helped in the teaching and training of health and allied medical science students.

Thank you.

A PhD would also not be completed without the help of the many people that contribute towards the project especially during the different stages. I would like to extend my warmest gratitude to the following persons during my studies.

To my principal supervisor, Prof Maciej Henneberg: this enormous task would not have been completed without his encouragement, support, invaluable advice, persistence, time, knowledge, patience and understanding. Thank you Maciej for the great opportunities I was offered during this time. To Dr Carl Stephan, thanks for showing me a different way of thinking when I got a bit lost and for all the advice for completing this task. A very special thank you to Dr Ellie Simpson for stepping in during a very difficult time of my PhD. I would like to thank her for reading the drafts so quickly and always offering encouragement to complete this PhD.

The University of Adelaide is thanked for the opportunity to come to Australia and for an International Postgraduate Research Scholarship during the course of my study. I am also grateful to all members of the Discipline of Anatomical Sciences, University of Adelaide for making me feel at home and accustomed me to the traditions and values of Australia, especially Bruce Firth, who always offered good advice and a helping hand throughout, Rachel Norris who always looked at the more humorous side of life and who stepped in when Maciej was unavailable. I would also

like to thank Tavik Morgenstern for answering all my “IT” and “Excel” questions and for all the help with the formatting of my thesis.

A special thank you to the University of the Witwatersrand, especially the School of Anatomical Sciences for access to the Dart Collection and also the hospitality offered during the time of my data collection. Elijah Mofokeng, Portia Mamiane and Sonnyboy Moshapo are also thanked for their assistance with the retrieval of specimens from the Collection on short notice. The following persons are also thanked for their assistance during the time of data collection: Paul Manger (Anatomical Sciences), Claire Gibbs and Justin Leonard (Donald Gordon Medical Centre: X-ray Department), and members of the School of Anatomical Sciences.

Nancy Briggs is thanked for her statistical advice and analyses of the data, Jill Evans from the South Australian Museum for the very early editions of the American Journal of Physical Anthropology, and the Library Staff at the University of Adelaide for acquiring some of the oldest reading material for this study.

Thank you to Antonina & Adhra for the support during this time as we were all in the ‘same’ boat. To Jane and Nadia, thanks for keeping me sane and making sure I still see the light of day every so often. To fellow PhD students: Jo, Francesca, Nilanga, Kari, Rebecca and the Honours students, thank you for the support.

To my parents: DAD, MUM, Darshana, Jayeshbhai, Chetnabhabi and the kids for their continuous love, support and understanding of my goals in life.

Last, but definitely not the least: I would like to thank Srikanth Prathipati whom I met during the writing of my thesis and who always encouraged me to finish the thesis. Thank you for sitting up with me many times and sacrificing your time just to keep me company during the gruelling hours of intense writing. My sincerest appreciation to you.
